

**AAPG Annual Convention
Calgary, June 2005**

Integrated model in Badley's TrapTester¹

[TW0516_1 Introduction](#)

We arrived at the tail end of one of the wettest periods in Southern Alberta's history – the province looked like a swamp as we landed. But the next day, and for the duration of the AAPG, the sun shone and the AAPG conference broke its post-1980s boom attendance record with a final count of 7,748 (the all-time record is around 13,000).

We were impressed by Exxon-Mobil's **Reservoir Evaluation Time Reduction (RETR)**, the interpretational equivalent of 'extreme programming' as presented by Lester Landis. Landis argues, *inter alia*, that super computer power should be used, not to build bigger models, but to build more models to test and evaluate multiple hypotheses.

Chevron has also been addressing the problems of multiple models, in particular, the potentially enormous combination of geological and flow models that need to be evaluated. Here, Chevron is an enthusiastic user and proselytizer for '**Design of Experiment**' statistical techniques derived from statistical work done early in the 20th century by statistician Ron Fisher.

Another significant driver in modeling and interpretation comes from BP's geological toolkit run-off and '**co-visualization**' research effort. BP is trying to get software vendors to offer simultaneous views of multiple domain models – geomodel plus attributes or reservoir flow simulation etc.

The seismic processing industry, according to a Schlumberger presentation, no longer considers itself '**CPU-bound**' – only 20% of the workflow involves a CPU wait. The rest of the time is spent interpreting and managing the data workflow – which has of course grown to more than fill the time gained by faster computers!

GIS usage is widespread. Anadarko presented a sophisticated use of geoprocessing to filter attributes according to proximity to geobodies. This appears to involve a considerable amount of data juggling between interpretation systems, ESRI and other image processing tools. Most vendors appear to have limited use and or requirements for geoprocessing and are more concerned with geodata management (even if this just involves Shapefile import) and web access to geo data. Others have equivalent functionality built into their applications (non GIS-solutions).

More generally it appears that **geological modeling** is expanding in scope to embrace tectonic plates, basins, source rocks, structures, fractures and more. Hitherto esoteric modeling is moving into mainstream prospect evaluation – posing a new set of problems of software and data integration.

¹ Images in this report have been contributed by the software vendors and authors concerned who hold copyright.

Schlumberger's new display was a model of roominess and frequentation. Roxar was conspicuous by its absence. Landmark was busy 're-igniting' Geographix, which now has a direct link to OpenWorks. Seismic Micro Technology president Tom Smith pointed us in the direction of a seminal presentation made by Leonhard Ganzer at the 2005 EAGE in Madrid. SMT was not showing this at the AAPG, but SMT's use of **graphics processing units** (GPU) in fluid flow simulation looks like potential breakthrough.

Highlights

[Reservoir Evaluation Time Reduction \(ExxonMobil\)](#)

TW0516_2 Awards Ceremony

There were no keynote speeches as such, although AAPG president Pat Graffon offered a brief recap of the AAPG’s activity during the last year. The AAPG now has 32,000 members, one third international. Membership is down from the boom years of the 1980s, but the number of committees is up! Challenges facing the industry today include a workforce shortage and increasing production from unconventional resources. To help in this, the AAPG has a ‘strategic plan’ – to ‘advance the science and profession of earth science worldwide’.

TW0516_2.1 Sidney Powers Award – Ken Glennie, Shell.

Glennie

Sidney Powers awardee, Ken Glennie (ex-Shell), author of the definitive Petroleum Geology of the North Sea gave an entertaining account of early work with Shell, investigating an apparent association between oil in Oman and nearby outcrops of oceanic basalts – which turned out to be tectonic serendipity. Declining a posting back to the UK in 1972, Glennie was banned from promotion for life, reflecting the ‘autocratic times’ of the day. Glennie became an educator, within Shell and outside—with publications on the petroleum geology of NW Europe, the desert of SW Arabia and most recently of the southern North Sea’s Permian basin.

TW0516_3 Geology/Modeling and Interpretation Sessions

TW0516_3.1 Seismic Geomorphology – Henry Posamentier et al., Anadarko

Posamentier presented a fireworks display of seismic geomorphology leveraging VoxelGeo, StratiMagic and image processing with ER Mapper. Seismic geomorphology has undergone a revolution – moving from the 2D internal reflection mapping of the past to 3D seismic volume interpretation. By changing cube transparency, fluvial patterns or carbonate patch reefs are revealed. A video of the Alaskan shelf showed stupendous imagery of sedimentary structures like crevasse splays, revealed by changing vertical relief and illumination angle. Such techniques can also identify ‘FLT’s, funny looking things—a ‘technical term’. Quantitative seismic geomorphology leverages geoprocessing with ESRI tools, to study channel sinuosity and center line mapping for automated channel counts.

TW0516_3.2 Reservoir Evaluation Time Reduction – Lester Landis, ExxonMobil

Lester Landis presented the E&P equivalent of ‘Extreme Programming,’ Reservoir Evaluation Time Reduction (RETR). This has produced a ‘step change’ in cycle time reduction for reservoir evaluation ‘without compromising interpretation quality’. Key enablers are Schlumberger’s Petrel and Exxon’s EPSIM and Power simulators. The idea is simple—build a simple model quickly and then refine it. EPSIM builds a
